(57) **ABSTRACT**

A self-configuring dynamic contact center including a plurality of resources, each resource associated with a set of attributes, a plurality of dynamic switches connected to the resources, a dynamic controller connected to the dynamic switches and configured to control the operation of the dynamic switches, and a routing engine connected to the dynamic controller. The routing engine is configured to utilize the dynamic controller and dynamic switches to determine the states of network paths between the dynamic switches, and is further configured to determine which of the resources are suitable to handle a contact based on requirements of the contact and the attributes of the resources, to determine which of the suitable resources is an optimal resource based on the requirements of the contact and the states of the network paths, and to utilize the dynamic controller and the dynamic switches to route the contact to the optimal resource.

SELF-CONFIGURING DYNAMIC CONTACT CENTER

BACKGROUND

1. Field of the Invention

Embodiments of the present invention provide a system and a method for managing a contact center. More particularly, embodiments of the present invention provide a system and a method for enabling a contact center to dynamically modify its routing configuration in response to variations in contacts and resources.

2. Description of Related Art

Contact centers are employed by many enterprises to service inbound and outbound communication with contacts/customers. A typical contact center includes a number of switches and routers for receiving and routing incoming packet-switched and/or circuit-switched contacts, and one or more resources, such as human agents and automated resources (e.g., Interactive Voice Response (IVR) units), to service the incoming contacts.

Contact centers distribute contacts, whether inbound or outbound, for servicing to any suitable resource according to predefined criteria. In many existing systems, the criteria for servicing a contact from the moment the contact center becomes aware of the contact until the contact is connected to an agent are client or operator-specifiable (i.e., programmable by the operator of the contact center), via a capability called vectoring. Normally, in present-day automatic call distribution (ACD), when an ACD system's controller detects an agent has become available to handle a contact, the controller identifies all predefined contact-handling queues for the agent (usually in some order of priority) and delivers to the agent the highest-priority, oldest contact that matches the agent's highest-priority queue. Generally, the only condition that results in a contact not being delivered to an available agent is where there are no contacts waiting to be handled.

The switches and routers that are employed in traditional contact center infrastructure and, more generally, in traditional computer/telecommunications infrastructure, are typically very large, very expensive, and are difficult to reconfigure once a particular network configuration has been established. Thus, while the use of such infrastructure may facilitate a reliable system, it also presents a number of drawbacks. For example, route configurations within the system do not change when resources (e.g., agents, automated media, etc.) are added or removed, resulting in inefficient network utilization. Furthermore, route configurations within the system do not change when networks become congested, because networks have no flexibility to adapt or reconfigure in response to changing traffic patterns. Still further, since switches are responsible for data forwarding and network control, their failure may have a detrimental effect on many other network components.

SUMMARY

In view of the foregoing, it would be advantageous to provide a system and method for enabling a contact center to dynamically modify its routing configuration in response to variations in contact requirements, contact center resources, and traffic patterns in order to optimize routing efficiency and reduce operating costs.

Embodiments in accordance with the present invention provide a self-configuring dynamic contact center. The contact center includes a plurality of resources, each resource associated with a set of attributes. The contact center further

2

includes a plurality of dynamic switches connected to the resources, a dynamic controller connected to the dynamic switches and configured to control the operation of the dynamic switches, and a routing engine connected to the dynamic controller. The routing engine is configured to utilize the dynamic controller and the dynamic switches to determine the states of network paths between the dynamic switches, and is further configured to determine which of the resources are suitable to handle a contact based on requirements of the contact and the attributes of the resources. The routing engine may further be configured to determine which of the suitable resources is an optimal resource based on the requirements of the contact and the states of the network paths, and to utilize the dynamic controller and the dynamic switches to route the contact to the optimal resource, or, the routing engine may be configured to determine which of a plurality of routes between the contact and a suitable resource is an optimal route based on the requirements of the contact and the states of the network paths, and to utilize the dynamic controller and the dynamic switches to route the contact to the suitable resource via the optimal route.

Embodiments in accordance with the present invention further provide a computer-implemented method for establishing a self-configuring dynamic contact center. The computer-implemented method includes receiving a contact at a dynamic switch network comprising a plurality of dynamic switches interconnected by network paths, identifying a plurality of resources within the contact center that are suitable for handling the contact, determining the states of the network paths, designating one of the suitable resources as an optimal resource based on the states of the network paths, and routing the contact to the optimal resource.

Embodiments in accordance with the present invention further provide a computer-implemented method for establishing a self-configuring dynamic contact center. This computer-implemented method includes receiving a contact at a dynamic switch network comprising a plurality of dynamic switches interconnected by network paths, identifying a resource within the contact center that is suitable for handling the contact, determining the states of the network paths, determining which of a plurality of routes between the contact and the suitable resource is an optimal route, and routing the contact to the suitable resource via the optimal route.

These and other advantages will be apparent from the disclosure of the present invention contained herein.

The preceding is a simplified summary of the present invention to provide an understanding of some aspects of the present invention. This summary is neither an extensive nor exhaustive overview of the present invention and its various embodiments. It is intended neither to identify key or critical elements of the present invention nor to delineate the scope of the present invention but to present selected concepts of the present invention in a simplified form as an introduction to the more detailed description presented below. As will be appreciated, other embodiments of the present invention are possible, utilizing, alone or in combination, one or more of the features set forth above or described in detail below.

BRIEF DESCRIPTION OF THE DRAWINGS

The above and still further features and advantages of the present invention will become apparent upon consideration of the following detailed description of embodiments thereof, especially when taken in conjunction with the accompanying drawings, and wherein:

FIG. 1 is a schematic diagram illustrating an exemplary self-configuring dynamic contact center in accordance with an embodiment of the present invention;

FIG. 2 is a schematic diagram detailing certain features of the exemplary self-configuring dynamic contact center shown in FIG. 1;

FIG. 3 is flow diagram illustrating an exemplary method of implementing the self-configuring dynamic contact center in accordance with an embodiment of the present invention; and

FIG. 4 is flow diagram illustrating another exemplary method of implementing the self-configuring dynamic contact center in accordance with an embodiment of the present invention.

The headings used herein are for organizational purposes only and are not meant to be used to limit the scope of the description or the claims. As used throughout this application, the word “may” is used in a permissive sense (i.e., meaning having the potential to), rather than the mandatory sense (i.e., meaning must). Similarly, the words “include,” “including,” and “includes” mean including but not limited to. To facilitate understanding, like reference numerals have been used, where possible, to designate like elements common to the figures.

DETAILED DESCRIPTION

The present invention will be illustrated below in conjunction with an exemplary communication system, e.g., the Avaya Aura® system. Although well suited for use with, e.g., a system having an ACD or other similar contact processing switch, the present invention is not limited to any particular type of communication system switch or configuration of system elements. Those skilled in the art will recognize the disclosed techniques may be used in any communication application in which it is desirable to provide improved contact processing.

The phrases “at least one,” “one or more,” and “and/or” are open-ended expressions that are both conjunctive and disjunctive in operation. For example, each of the expressions “at least one of A, B and C,” “at least one of A, B, or C,” “one or more of A, B, and C,” “one or more of A, B, or C” and “A, B, and/or C” means A alone, B alone, C alone, A and B together, A and C together, B and C together, or A, B and C together.

The term “a” or “an” entity refers to one or more of that entity. As such, the terms “a” (or “an”), “one or more” and “at least one” can be used interchangeably herein. It is also to be noted the terms “comprising,” “including,” and “having” can be used interchangeably.

The term “automatic” and variations thereof, as used herein, refers to any process or operation done without material human input when the process or operation is performed. However, a process or operation can be automatic, even though performance of the process or operation uses material or immaterial human input, if the input is received before performance of the process or operation. Human input is deemed to be material if such input influences how the process or operation will be performed. Human input that consents to the performance of the process or operation is not deemed to be “material.”

The term “computer-readable medium” as used herein refers to any tangible storage and/or transmission medium that participate in providing instructions to a processor for execution. Such a medium may take many forms, including but not limited to, non-volatile media, volatile media, and transmission media. Non-volatile media includes, for example, NVRAM, or magnetic or optical disks. Volatile

media includes dynamic memory, such as main memory. Common forms of computer-readable media include, for example, a floppy disk, a flexible disk, hard disk, magnetic tape, or any other magnetic medium, magneto-optical medium, a CD-ROM, any other optical medium, punch cards, paper tape, any other physical medium with patterns of holes, a RAM, a PROM, and EPROM, a FLASH-EPROM, a solid state medium like a memory card, any other memory chip or cartridge, a carrier wave as described hereinafter, or any other medium from which a computer can read.

A digital file attachment to e-mail or other self-contained information archive or set of archives is considered a distribution medium equivalent to a tangible storage medium. When the computer-readable media is configured as a database, it is to be understood that the database may be any type of database, such as relational, hierarchical, object-oriented, and/or the like. Accordingly, the present invention is considered to include a tangible storage medium or distribution medium and prior art-recognized equivalents and successor media, in which the software implementations of the present invention are stored.

The terms “determine,” “calculate” and “compute,” and variations thereof, as used herein, are used interchangeably and include any type of methodology, process, mathematical operation or technique.

The terms “component” and “module” as used herein refer to any known or later developed hardware, software, firmware, artificial intelligence, fuzzy logic, or combination of hardware and software that is capable of performing the functionality associated with the referenced element. Also, while the present invention is described in terms of exemplary embodiments, it should be appreciated those individual aspects of the present invention can be separately claimed.

The term “switch” or “server” as used herein should be understood to include a PBX, an ACD, an enterprise switch, or other type of communications system switch or server, as well as other types of processor-based communication control devices such as media servers, computers, adjuncts, etc.

FIG. 1 shows an illustrative embodiment of a self-configuring dynamic contact center **100** (hereinafter “the contact center **100**”) in accordance with the present invention. The contact center **100** may include a session manager **110**, a set of data stores or databases **114** containing contact or customer related information and other information that can enhance the value and efficiency of contact processing, and a plurality of servers, namely a media server **118**, an interactive response unit (e.g., IVR) **122**, a routing engine **126**, and switches **130_{1-N}**, all interconnected by a local area network LAN (or wide area network WAN) **142** or other network connection technologies. A plurality of working agents operating packet-switched 1st agent communication devices **134_{1-N}** (such as computer work stations or personal computers), and/or circuit-switched 2nd agent communication devices **138_{1-N}** may be connected to respective switches **130_{1-N}**. The session manager **110** is further connected to a circuit switched network **154** (e.g., a Public Switch Telephone Network or PSTN) and a packet switched network **162** (e.g., a distributed processing network, such as the Internet). The packet-switched network **162** is in communication with one or more external 1st contact communication devices **169**, and the circuit-switched network **154** with one or more external 2nd contact communication devices **180**, used by customers to communicate with the contact center **100**. A session border controller **158** is positioned between the session manager **110** and the networks **154** and **162** for processing communications passing between the session manager **110** and the networks **154** and **162** as further described below.

Although the preferred embodiment is discussed with reference to client-server architecture, it is to be understood that the principles of the present invention apply to other network architectures. For example, the present invention applies to peer-to-peer networks, such as those envisioned by the Session Initiation Protocol. In the client-server model or paradigm, network services and the programs used by end users to access the services are described. The client side provides a user with an interface for requesting services from the network, and the server side is responsible for accepting user requests for services and providing the services transparent to the user. By contrast in the peer-to-peer model or paradigm, each networked host runs both the client and server parts of an application program.

Additionally, the present invention does not require the presence of packet- or circuit-switched networks. The term "switch" or "server" as used herein should be understood to include a PBX, an ACD, an enterprise switch, an enterprise server, or other type of telecommunications system switch or server, as well as other types of processor-based communication control devices such as media servers, computers, adjuncts, etc.

In one embodiment, the session border controller **158** of the contact center **100** may be Avaya Inc.'s, G700 Media Gateway.TM, which may be implemented as a hardware component, such as via an adjunct processor or as a chip onboard the server. The session border controller **158** is responsible for providing the contact center **100** with a security gateway for protecting the contact center **100** from malicious attacks, toll fraud, malformed packets, and the like. It will be appreciated by those of ordinary skill in the art that the session border controller **158** may perform a variety of other functions, such as facilitating network connectivity, monitoring quality of service, and providing regulatory support.

The session manager **110** is responsible for routing and managing contacts inside of the contact center **100** (i.e., after the contacts have been admitted to the contact center **100** by the session border controller **158**). Particularly, the session manager **110** communicates with the other SIP enabled devices (e.g., the media server **118**, IVR **122**, routing engine **126**, and switches **130_{1-N}**) in the contact center **100** and is configured with routing and dial plans to facilitate appropriate forwarding of incoming contacts as designated by the routing engine **126** as further described below.

The routing engine **126** is responsible for determining where, within the contact center **100**, incoming contacts should be routed to and notifying the session manager **110** accordingly. For example, the routing engine **126** may receive a notification from the session manager **110** indicating that an incoming contact has been received. The routing engine **126** may then scan an internal database for available resources (e.g., agents, the media server **118**, etc.) within the contact center **100** which are best suited to handle that particular contact. The routing engine **126** may access customer/contact information stored in the database(s) **114** in order to make such a determination. The routing engine **126** may then transmit a response back to the session manager **110** indicating the specific resource to which the contact should be routed. For example, the routing engine **126** may indicate to the session manager **110** that, based on the language requirements of a particular contact, that contact should be routed to an appropriate agent at a particular one of the 1st agent communication devices **134_{1-N}** via a respective one of the switches **130_{1-N}**.

The IVR **122** provides an interactive, automated menu system for allowing incoming contacts to at least partially navigate to an appropriate resource within the contact center **100**. For example, an incoming contact may be connected to

the IVR **122**, may select options to navigate through an automated menu, and may thereby be connected to an appropriate/desired resource without tying up contact center personnel. The IVR **122** may also perform other functions that will be familiar to those of ordinary skill in the art, such as allowing a contact to select a preferred language of communication, based on which the IVR system may intelligently route the contact to an agent who is fluent in the selected language.

The media server **118** of the contact center **100** is responsible for playing treatment messages for contacts when appropriate. Such treatment messages may include prerecorded announcements (e.g., "an agent will be with you shortly"), on-hold music, etc. The particular format of the treatment message may depend on the type of contact received. For example, video chat contacts may receive video messages, while phone call contacts may receive voice messages.

The first agent communication devices **134_{1-N}** are packet-switched devices that may include, for example, IP hardphones such as the Avaya Inc.'s, 4600 Series IP Phones.TM, IP softphones such as Avaya Inc.'s, IP Softphone.TM, Personal Digital Assistants or PDAs, Personal Computers or PCs, laptops, packet-based H.320 video phones and conferencing units, packet-based voice messaging and response units, packet-based traditional computer telephony adjuncts, peer-to-peer based communication devices, and any other communication device.

The second agent communication devices **138_{1-N}** are circuit-switched devices. Each of the second agent communication devices **138_{1-N}** corresponds to one of a set of internal extensions Ext_{1-N}, respectively. The second agent communication devices **138_{1-N}** can include, for example, wired and wireless telephones, PDAs, H.320 videophones and conferencing units, voice messaging and response units, traditional computer telephony adjuncts, and any other communication device.

It should be noted that the present invention does not require any particular type of information transport medium between switch or server and first and second communication devices, i.e., the present invention may be implemented with any desired type of transport medium as well as combinations of different types of transport channels.

It should be emphasized that the particular configuration of the contact center **100** shown in FIG. 1, including all of the components thereof, is presented for purposes of illustration only and should not be construed as limiting the present invention to any particular arrangement of elements.

Referring to FIG. 2, a simplified schematic representation of the contact center **100** is illustrated (in which certain components of the contact center **100** shown in FIG. 1 are omitted for clarity) for presenting certain aspects of the contact center **100** in greater detail. Particularly, the switches **130₁₋₄** of the contact center **100** are OpenFlow enabled switches that are operatively connected to an OpenFlow controller **160** (described in greater detail below) that receives instructions from, and may be implemented as an integral component of, the routing engine **126** of the call center **100**.

As will be recognized by those of ordinary skill in the art, OpenFlow is an open communications protocol that may be added to commercial Ethernet switches, routers and wireless access points to enable certain routing control features not found in conventional routers or switches. For example, in a conventional router or switch, fast packet forwarding (data path) and high level routing decisions (control path) occur on the same device. By contrast, OpenFlow enabled switches, such as the switches **130₁₋₄**, separate data path and control path functions. Particularly, the data path portions reside on

the switches 130_{1-4} while high-level routing decisions reside a separate controller, such as the OpenFlow enabled controller **160**. The OpenFlow enabled switches 130_{1-4} and controller **160** communicate via OpenFlow protocol, which defines messages, such as packet-received, send-packet-out, modify-forwarding-table, and get-stats. The implementation and operation of the various OpenFlow components in the contact center **100** will be described in greater detail below.

It should be noted that the switches 130_{1-4} and controller **160** may alternatively or additionally be enabled with any other software packages or systems (i.e., other than OpenFlow) that facilitate similar, dynamically controllable routing. Therefore, the switches 130_{1-4} and controller **160** will hereinafter be referred to as the “dynamic switches 130_{1-4} ” and the “dynamic controller **160**,” such terminology defined herein to encompass OpenFlow enabled switches and controllers as well as switches and controllers enabled with other, similar technologies that are known in the art or that have yet to be developed.

Still referring to FIG. 2, a plurality of contacts 170_{1-4} are connected to the packet-switched network **162** and/or the circuit-switched network **154**, such as via the 1st and 2nd contact communication devices **169** and **180** shown in FIG. 1. The packet-switched network **162** and the circuit-switched network **154** are connected to the dynamic switches 130_{1-4} , such as via the session border controller **158** and the session manager **110** shown in FIG. 1. The dynamic switches 130_{1-4} route contact traffic to and from a plurality of agents 172_{1-7} who are equipped with the 1st and/or 2nd agent communication devices 134_{1-N} and 138_{1-N} shown in FIG. 1.

The dynamic switches 130_{1-4} are interconnected by network paths 174_{1-6} , and are connected to the dynamic controller **160** by control channels 176_{1-4} . The dynamic controller **160** may thereby transmit instructions to the dynamic switches 130_{1-4} that dictate the manner in which contact traffic is routed between the dynamic switches 130_{1-4} and to the agents 172_{1-7} in accordance with routing decisions made by the routing engine **126**. In order to make such routing decisions, the routing engine **126** monitors the attributes/skill sets of all of the active agents 172_{1-7} (or other resources) in the contact center **100**. For example, the routing engine **126** may determine which agents 172_{1-7} have video call capability, what languages each of the agents 172_{1-7} speaks, what the agents’ respective areas of expertise are, etc. Additionally, by virtue of the communication between the dynamic controller **160** and the dynamic switches 130_{1-4} , the dynamic controller **160** enables the routing engine **126** to continuously monitor the states of the network paths 174_{1-6} between the dynamic switches 130_{1-4} . Thus, by correlating the requirements of each contact 170_{1-4} (e.g., language requirements, communication device requirements, bandwidth requirements, etc.) with the attributes of available resources and the current traffic levels between the dynamic switches 130_{1-4} , the routing engine **126** may determine the best manner in which to route contact traffic in order to most efficiently utilize contact center resources and optimize customer/contact experience.

The routing engine **126** may use the dynamic controller **160** and the dynamic switches 130_{1-4} to implement the above-described intelligent routing scheme in either a “passive” manner, wherein contact center resources are allocated based on the monitored state of the switch network, or an “active” manner, wherein the switch network is monitored and actively modified in order to direct traffic to contact center resources in an optimal manner.

In an illustrative, non-limiting example of a passive implementation of the contact center **100**, the contact 170_1 in FIG. 2 is a high priority customer who places a video call to the

contact center **100** which arrives at the dynamic switch 130_1 . The contact 170_1 may then be presented with a treatment message by the media server **118** while the routing engine **126** identifies agents 172_{1-7} having attributes best suited to handle the call. In this example, the agents 172_1 and 172_4 both have skill sets that are suitable for the contact 170_1 , are both equipped to handle video calls, and are both currently available, and are therefore both eligible for selection by the routing engine **126**. However, the network path 174_1 between the dynamic switch 130_1 and the dynamic switch 130_3 is currently heavily utilized and has limited available bandwidth for handling a video call without compromising call quality (i.e., audio and/or video quality).

In conventional contact centers, the state of the network paths 174_{1-6} would not be taken into account when selecting an agent 172_{1-7} to handle the contact, which could result in a suboptimal agent selection (e.g., agent 172_1 is less preferable in this example because the network path 174_1 leading to agent 172_1 is congested and is not suitable for supporting a video call). However, in the dynamic contact center **100** of the present disclosure, the dynamic controller **160** and the dynamic switches 130_{1-4} enable the routing engine **126** to monitor the state of the network paths 174_{1-6} as described above, and to therefore make an informed routing decision in view of current system loads.

In the present example, the routing engine **126** would utilize the dynamic controller **160** and the dynamic switches 130_{1-4} to route the contact 170_1 to the agent 172_4 (i.e., via the less congested network path 174_5 between dynamic switch 130_1 and dynamic switch 130_4) instead of to the agent 172_1 , thereby providing the contact 170_1 with a higher quality video call and a better customer experience. The agent 172_4 in this scenario may therefore be termed the “optimal resource,” selected from a plurality of suitable resources. However, if the contact 170_1 was a low priority contact and/or did not require a great deal of bandwidth for a suitable connection (e.g., if the contact 170_1 was a voice call), the routing engine **126** might utilize the dynamic controller **160** and the dynamic switches 130_{1-4} to route the contact 170_1 to the agent 172_1 , thereby leaving the agent 172_4 available for contacts who have higher priority and/or require greater bandwidth connections. The “optimal resource” in such a scenario would therefore be the agent 172_1 .

In an illustrative, non-limiting example of the active implementation of the contact center **100**, the contact 170_1 in FIG. 2 is again a high priority customer who places a video call to the contact center **100** which arrives at the dynamic switch 130_1 . As in the passive implementation example above, the contact 170_1 may then be played a treatment message by the media server **118** while the routing engine **126** identifies an agent 172_{1-7} who is best suited to handle the call. In this example, only the agent 172_1 is available and has the skill set and equipment necessary for handling the requirements of contact 170_1 . However, as in the example above, the network path 174_1 between the dynamic switch 130_1 and the dynamic switch 130_3 is currently heavily utilized and has limited available bandwidth for handling a video call without compromising call quality.

In conventional contact centers, the contact 170_1 might be routed to the agent 172_1 via the network path 174_1 , despite the heavy congestion thereof, due to a static, preconfigured routing scheme. However, in the dynamic contact center **100** of the present disclosure, the dynamic controller **160** and the dynamic switches 130_{1-4} enable the routing engine **126** to dynamically modify the route between a contact and a specific resource in view of system loads. In the present example, the routing engine **126** would utilize the dynamic controller

160 and the dynamic switches 130₁₋₄ to route the contact 170₁ to agent 172₁ via the less congested network paths 174₅ and 174₂ (or network paths 174₄ and 174₅) instead of the highly congested network path 174₁, thereby providing the contact 170₁ with a higher quality call and a better customer experience. The network paths 174₅ and 174₂ in this scenario may therefore be termed the “optimal route,” selected from a plurality of suitable routes.

However, if the contact 170₁ was a low priority contact and/or did not require a great deal of bandwidth for a suitable connection, the routing engine 126 might utilize the dynamic controller 160 and the dynamic switches 130₁₋₄ to route the contact 170₁ to the agent 172₁ via the network path 174₁, thereby leaving the less congested network paths 174₅ and 174₂ available for contacts who have higher priority and/or require greater bandwidth connections. The “optimal route” in such a scenario would therefore be the network path 174₁.

Referring to FIG. 3, a flow diagram illustrating an exemplary method for implementing the above-described passive routing scheme of the self-configuring dynamic contact center 100 in accordance with the present disclosure is shown. Such method will now be described in conjunction with the schematic representation of the contact center 100 shown in FIG. 2.

At a first step 300 of the exemplary method, a contact 170₁₋₄ may initiate communication with the contact center 100, such as via the 1st and 2nd contact communication devices 169 and 180 shown in FIG. 1. The contact 170₁₋₄ may then, at step 310, be received at one of the dynamic switches 130₁₋₂. At optional step 320, a treatment message provided by the media server 118 may be presented to the contact 170₁₋₄.

At step 330 of the exemplary method, the routing engine 126 may determine which of the active agents 172₁₋₇ are best suited to handle the contact 170₁₋₄ based on the attributes, skill sets, and availability of the agents 172₁₋₇. The routing engine 126 may then, at step 340, use the dynamic controller 160 to query the dynamic switches 130₁₋₄ to determine the traffic loads (e.g., queues) on the network paths 174₁₋₆.

At step 350 of the exemplary method, the routing engine 126 may correlate the requirements of the contact 170₁₋₄ (e.g., language requirements, communication device requirements, bandwidth requirements, etc.) the traffic loads on the network paths 174₁₋₆ in order to determine which of the suitable agents 172₁₋₇ is an optimal resource that the contact 170₁₋₄ should be routed to in order to most efficiently utilize the network paths 174₁₋₅ while providing the contact 170₁₋₄ with a high quality experience.

For example, if the contact 170₁₋₄ is a video call that requires high bandwidth for a robust, high quality connection, the routing engine 126 may determine that the contact 170₁₋₄ should be routed to a suitable agent 172₁₋₇ that is accessible via a route that has a low level of traffic and high available bandwidth. Conversely, if the contact 170₁₋₄ is a voice call that does not require a great deal of bandwidth, the routing engine 126 may determine that the contact 170₁₋₄ should be routed to a suitable agent 172₁₋₇ that is accessible via a more congested route, thereby leaving less congested routes available for contacts requiring high bandwidth connections.

At step 360, the routing engine 126 may utilize the dynamic controller 160 and the dynamic switches 130₁₋₄ to route the contact 170₁₋₄ to the optimal resource identified in step 350.

Referring to FIG. 4, a flow diagram illustrating an exemplary method for implementing the above-described active routing scheme of the self-configuring dynamic contact center 100 in accordance with the present disclosure is shown.

Such method will now be described in conjunction with the schematic representation of the contact center 100 shown in FIG. 2.

At a first step 400 of the exemplary method, a contact 170₁₋₄ may initiate communication with the contact center 100, such as via the 1st and 2nd contact communication devices 169 and 180 shown in FIG. 1. The contact 170₁₋₄ may then, at step 410, be received at one of the dynamic switches 130₁₋₂. At optional step 420, a treatment message provided by the media server 118 may be presented to the contact 170₁₋₄.

At step 430 of the exemplary method, the routing engine 126 may determine which of the active agents 172₁₋₇ is best suited to handle the contact 170₁₋₄ based on the attributes, skill sets, and availability of the agents 172₁₋₇. The routing engine 126 may then, at step 440, use the dynamic controller 160 to query the dynamic switches 130₁₋₄ to determine the traffic loads (e.g., queues) on the network paths 174₁₋₆.

At step 450 of the exemplary method, the routing engine 126 may determine, from the traffic loads on the network paths 174₁₋₆, an optimal route between the contact 170₁₋₄ and the best suited agent 172₁₋₇ (identified in step 430) that will efficiently utilize the network paths 174₁₋₅ while providing the contact 170₁₋₄ with a high quality experience. For example, if the contact 170₁₋₄ is a video call that requires high bandwidth for a robust, high quality connection, the routing engine 126 may determine that the contact 170₁₋₄ should be routed to the best suited agent 172₁₋₇ via a route that has a low level of traffic and high available bandwidth. Conversely, if the contact 170₁₋₄ is a voice call that does not require a great deal of bandwidth, the routing engine 126 may determine that the contact 170₁₋₄ should be routed to the best suited agent 172₁₋₇ via a more congested route, thereby leaving less congested routes available for contacts requiring high bandwidth connections.

At step 460, the routing engine 126 may utilize the dynamic controller 160 to reconfigure the dynamic switches 130₁₋₄ to route the contact 170₁₋₄ to the best suited agent 172₁₋₇ via the optimal route identified in step 450.

It will be appreciated from the above description that the embodiments of the contact center 100 and corresponding methods provided herein enable dynamic modification of routing configurations in response to contact requirements, variations in contact center resources, and traffic patterns, thereby optimizing contact center routing efficiency and reducing contact center operating costs.

The exemplary systems and methods of this present invention have been described in relation to a contact center. However, to avoid unnecessarily obscuring the present invention, the preceding description omits a number of known structures and devices. This omission is not to be construed as a limitation of the scope of the claimed invention. Specific details are set forth to provide an understanding of the present invention. It should however be appreciated that the present invention may be practiced in a variety of ways beyond the specific detail set forth herein.

Furthermore, while the exemplary embodiments of the present invention illustrated herein show the various components of the system collocated, certain components of the system can be located remotely, at distant portions of a distributed network, such as a LAN and/or the Internet, or within a dedicated system. Thus, it should be appreciated that the components of the system can be combined in to one or more devices, such as a switch, server, and/or adjunct, or collocated on a particular node of a distributed network, such as an analog and/or digital telecommunications network, a packet-switch network, or a circuit-switched network.

It will be appreciated from the preceding description, and for reasons of computational efficiency, that the components of the system can be arranged at any location within a distributed network of components without affecting the operation of the system. For example, the various components can be located in a switch such as a PBX and media server, gateway, in one or more communications devices, at one or more users' premises, or some combination thereof. Similarly, one or more functional portions of the system could be distributed between a telecommunications device(s) and an associated computing device.

Furthermore, it should be appreciated the various links connecting the elements can be wired or wireless links, or any combination thereof, or any other known or later developed element(s) that is capable of supplying and/or communicating data to and from the connected elements. These wired or wireless links can also be secure links and may be capable of communicating encrypted information. Transmission media used as links, for example, can be any suitable carrier for electrical signals, including coaxial cables, copper wire and fiber optics, and may take the form of acoustic or light waves, such as those generated during radio-wave and infra-red data communications.

Also, while the flowcharts have been discussed and illustrated in relation to a particular sequence of events, it should be appreciated that changes, additions, and omissions to this sequence can occur without materially affecting the operation of the present invention.

A number of variations and modifications of the present invention can be used. It would be possible to provide for some features of the present invention without providing others.

For example, in one embodiment, the systems and methods of this present invention can be implemented in conjunction with a special purpose computer, a programmed microprocessor or microcontroller and peripheral integrated circuit element(s), an ASIC or other integrated circuit, a digital signal processor, a hard-wired electronic or logic circuit such as discrete element circuit, a programmable logic device or gate array such as PLD, PLA, FPGA, PAL, special purpose computer, any comparable means, or the like.

In general, any device(s) or means capable of implementing the methodology illustrated herein can be used to implement the various aspects of this present invention. Exemplary hardware that can be used for the present invention includes computers, handheld devices, telephones (e.g., cellular, Internet enabled, digital, analog, hybrids, and others), and other hardware known in the art. Some of these devices include processors (e.g., a single or multiple microprocessors), memory, nonvolatile storage, input devices, and output devices. Furthermore, other software implementations including, but not limited to, distributed processing or component/object distributed processing, parallel processing, or virtual machine processing can also be constructed to implement the methods described herein.

In yet another embodiment of the present invention, the disclosed methods may be readily implemented in conjunction with software using object or object-oriented software development environments that provide portable source code that can be used on a variety of computer or workstation platforms. Also, the disclosed system may be implemented partially or fully in hardware using standard logic circuits or VLSI design. Whether software or hardware is used to implement the systems in accordance with this present invention is dependent on the speed and/or efficiency requirements of the

system, the particular function, and the particular software or hardware systems or microprocessor or microcomputer systems being utilized.

In yet another embodiment of the present invention, the disclosed methods may be partially implemented in software that can be stored on a storage medium, executed on programmed general-purpose computer with the cooperation of a controller and memory, a special purpose computer, a microprocessor, or the like. In these instances, the systems and methods of this present invention can be implemented as program embedded on personal computer such as an applet, JAVA® or CGI script, as a resource residing on a server or computer workstation, as a routine embedded in a dedicated measurement system, system component, or the like. The system can also be implemented by physically incorporating the system and/or method into a software and/or hardware system.

Although the present invention describes components and functions implemented in the embodiments with reference to particular standards and protocols, the present invention is not limited to such standards and protocols. Other similar standards and protocols not mentioned herein are in existence and are considered to be included in the present invention. Moreover, the standards and protocols mentioned herein and other similar standards and protocols not mentioned herein are periodically superseded by faster or more effective equivalents having essentially the same functions. Such replacement standards and protocols having the same functions are considered equivalents included in the present invention.

The present invention, in various embodiments, configurations, and aspects, includes components, methods, processes, systems and/or apparatus substantially as depicted and described herein, including various embodiments, sub-combinations, and subsets thereof. Those of skill in the art will understand how to make and use the present invention after understanding the present disclosure. The present invention, in various embodiments, configurations, and aspects, includes providing devices and processes in the absence of items not depicted and/or described herein or in various embodiments, configurations, or aspects hereof, including in the absence of such items as may have been used in previous devices or processes, e.g., for improving performance, achieving ease and/or reducing cost of implementation.

The foregoing discussion of the present invention has been presented for purposes of illustration and description. The foregoing is not intended to limit the present invention to the form or forms disclosed herein. In the foregoing Detailed Description for example, various features of the present invention are grouped together in one or more embodiments, configurations, or aspects for the purpose of streamlining the disclosure. The features of the embodiments, configurations, or aspects of the present invention may be combined in alternate embodiments, configurations, or aspects other than those discussed above. This method of disclosure is not to be interpreted as reflecting an intention that the claimed invention requires more features than are expressly recited in each claim. Rather, as the following claims reflect, inventive aspects lie in less than all features of a single foregoing disclosed embodiment, configuration, or aspect. Thus, the following claims are hereby incorporated into this Detailed Description, with each claim standing on its own as a separate preferred embodiment of the present invention.

Moreover, though the description of the present invention has included description of one or more embodiments, configurations, or aspects and certain variations and modifications, other variations, combinations, and modifications are within the scope of the present invention, e.g., as may be

13

within the skill and knowledge of those in the art, after understanding the present disclosure. It is intended to obtain rights which include other embodiments, configurations, or aspects to the extent permitted, including alternate, interchangeable and/or equivalent structures, functions, ranges or steps to those claimed, whether or not such alternate, interchangeable and/or equivalent structures, functions, ranges or steps are disclosed herein, and without intending to publicly dedicate any patentable subject matter.

What is claimed is:

1. A dynamic contact center comprising:

a plurality of resources, each resource being associated with a respective set of attributes;

a plurality of dynamic switches connected to the resources, wherein the dynamic switches are interconnected by network paths and each dynamic switch comprises a respective data path separate from a respective control path;

a dynamic controller connected to each of the dynamic switches via the respective control path of the dynamic switch to control the operation of the dynamic switches; and

a server in communication with the dynamic controller, the server comprising:

a computer-readable storage medium, storing executable instructions; and

a processor in communication with the computer readable storage medium, the processor when executing the executable instructions:

continuously monitors states of the network paths between the dynamic switches based on information related to the states of the network paths received from the dynamic controller;

determines which of the plurality of resources is suitable to handle the contact based on requirements of the contact and the associated respective sets of attributes of the resources;

determines which of the suitable resources is an optimal resource based on the requirements of the contact and the continuously monitored states of the network paths;

determines a route through the dynamic switches for a dynamic contact center contact to the optimal resource of the dynamic contact center based on the associated respective sets of attributes of the resources and the continuously monitored states of the network paths; and

transmits the determined route to the dynamic controller.

2. The dynamic contact center of claim 1, wherein the processor when executing the executable instructions utilizes the dynamic controller and the dynamic switches to route the contact to the optimal resource.

3. The dynamic contact center of claim 1, wherein the processor when executing the executable instructions determines which of a plurality of routes between the contact and the suitable resource is an optimal route based on the requirements of the contact and the continuously monitored states of the network paths.

4. The dynamic contact center of claim 3, wherein the the processor when executing the executable instructions utilizes the dynamic controller and the dynamic switches to route the contact to the suitable resource via the optimal route.

5. A method of dynamically routing a contact received at a dynamic switch network of a contact center, the dynamic switch network comprising a plurality of dynamic switches interconnected by network paths, the method comprising:

14

identifying, by a processor, a plurality of resources within the contact center that are suitable for handling the contact, wherein the plurality of dynamic switches are connected to the resources, each resource being associated with a respective set of attributes;

continuously monitoring, by the processor in communication with a dynamic controller, states of the network paths between the dynamic switches,

wherein each dynamic switch comprises a respective data path separate from a respective control path; and wherein the dynamic controller is connected to each of the dynamic switches via the respective control path of the dynamic switch to control operation of the dynamic switches;

designating, by the processor, one of the suitable resources as an optimal resource based on the continuously monitored states of the network paths and requirements of the contact;

determining, by the processor, routing instructions for routing the contact to the optimal resource via the dynamic switch network based on the associated respective sets of attributes of the resources and the continuously monitored states of the network paths; and

transmitting, by the processor, the routing instructions to the dynamic controller.

6. The method in accordance with claim 5, wherein the step of identifying a plurality of resources within the contact center that are suitable to handle the contact comprises comparing, by the processor, the requirements of the contact with the associated respective sets of attributes of the resources.

7. The method in accordance with claim 5, wherein the step of continuously monitoring the states of the network paths comprises receiving, by the processor, information related to the states of the network paths from the dynamic controller.

8. The method in accordance with claim 5, wherein the step of designating one of the suitable resources as an optimal resource based on the continuously monitored states of the network paths comprises determining, by the processor, which of the suitable resources is accessible by a most appropriate route.

9. The method in accordance with claim 8, wherein the most appropriate route is a least congested route compared to other routes to the suitable resources.

10. The method in accordance with claim 8, wherein the most appropriate route is a most congested route compared to other routes to the suitable resources.

11. A method of dynamically routing a contact received at a dynamic switch network of a contact center, the dynamic switch network comprising a plurality of dynamic switches interconnected by network paths and the contact center comprising a plurality of resources, the method comprising:

identifying, by a processor, which of the plurality of resources within the contact center are suitable for handling the contact, wherein the plurality of dynamic switches are connected to the resources, each resource being associated with a respective set of attributes;

continuously monitoring, by the processor in communication with a dynamic controller, states of the network paths between the plurality of dynamic switches,

wherein each dynamic switch comprises a respective data path separate from a respective control path; and wherein the dynamic controller is connected to each of the dynamic switches via the respective control path of the dynamic switch to control operation of the dynamic switches;

designating, by the processor, one of the suitable resources as an optimal resource based on the continuously monitored states of the network paths and requirements of the contact;

determining, by the processor, which of a plurality of routes between the contact and the suitable resource is an optimal route through the dynamic switch network based on the associated respective sets of attributes of the resources and the continuously monitored states of the network paths; and

transmitting, by the processor, routing instructions for the optimal route to the dynamic controller.

12. The method in accordance with claim 11, wherein the step of continuously monitoring the states of the network paths comprises receiving, by the processor, information related to the states of the network paths from the dynamic controller.

13. The method in accordance with claim 11, wherein the step of determining which of a plurality of routes between the contact and the one of the plurality of resources is an optimal route comprises correlating, by the processor, requirements of the contact with the continuously monitored states of the network paths.

14. The method in accordance with claim 11, wherein routing instructions for the optimal route comprises instructions for reconfiguring the dynamic switches to route the contact to the one of the plurality of resources via one or more of the network paths in accordance with the optimal route.
